Diagnostics A: Overview	What diagnostics are most beneficial depend on what one is modeling

Diagnostics are *extremely* important. Without effective diagnostics even a correct and well converged simulation is useless. Diagnostics must be well formulated to display relevant quantities in a manner that increases physical understanding by highlighting important processes. This can be difficult since there can be a variety of issues and multiple effects taking place simultaneously.

Diagnostics can be grouped into two broad categories:

1) Snapshot Diagnostics

(Fixed instant in time)

- Examples: Plots of particle distribution projections at a particular values of s or t
- Data can be saved to generate plots after the run or just the needed plots can be generated during the run using linked graphics packages etc.
- Sometimes presented as a sequence of images (movie) to show evolution

2) History Diagnostics

(Time history of evolution)

- Examples: plots of moment for the statistical beam centroid, envelope, and emittances
- Data for history plots must be accumulated and saved over several simulation advance steps

SM Lund, USPAS, 2016

Self-Consistent Simulations 3

- Can be highly specific to the problem
- Use quantities people are familiar with to most effectively communicate
- May need different targeted diagnostics for physics applications and detailed verification/benchmarking of simulations/algorithms

Diagnostics plots can be generated in a variety of ways

- Routines within the code
- Best to be flexible: easily reconfigured to context needed
- Python diagnostic scripts in Warp provide considerable flexability
- Dumping organized data for post processing
- Organization important: storage requirements can be large

Can be effective to numerically synthesize laboratory equivalent diagnostics to ease left right comparisons with experiment

- Experiments very difficult and making context as similar as possible can alleviate confusion
- Simulations can simultaneously measure many quantities: if limited context synthetic diagnostics agree with experiment, it can increase confidence in broader implications of the simulation data which may not be easily measured

Old Saying:	A picture is worth a thousand words	
Present Context?:	A good diagnostic plot is worth TBs of data	
SM Lund, USPAS, 2016	Self-Consistent Simulations	4

Lattice elements modeled at high levels of detail for importing into simulations

Moments

Commonly gathered over a moving window over the beam pulse - Example: Pulse current, transverse rms beam extent and rms emittance as a function of z over beam pulse $I(z) = \int d^2x \ J_z(\mathbf{x}, t = \text{const})$ Beam current: $r_x(z) = 2\langle x^2 \rangle_{\perp}^{1/2}$ Perp rms extent: $\varepsilon_x(z) = 4 \left[\langle x^2 \rangle_\perp \langle x'^2 \rangle_\perp - \langle xx' \rangle_\perp^2 \right]^{1/2}$ Perp rms emittance: Add mountain range plot in future version Movies Help illustrate trends and great for getting attention to topics. Correlated evolution of multiple quantities most useful but difficult to make. Will be posting Warp guidelines/tools soon. - Example: play in class: space-charge wave evolution + multispecies beam evolution FRIB movie from K. Fukushima (KEK/MSU) SM Lund, USPAS, 2016 Self-Consistent Simulations 6

History Diagnostics: Moment Evolutions

Time histories of quantities are highly useful. Common measures include

- Pulse energy, current
- Moments: center of mass phase-space, rms extents, emittances, etc

Histories of invariants can be particularly useful for checks of simulations

Moments:

Typically have a lesser degree of noise since they generally average over many macroparticles

 $\varepsilon_x = 4 \left[\langle x^2 \rangle_\perp \langle x'^2 \rangle_\perp - \langle xx' \rangle_\perp^2 \right]^{1/2}$

- \rightarrow 2D case => full beam
- \Rightarrow 3D case => local z-slice of beam

Examples:

Beam Current: $I = \int d^2x J_z(\mathbf{x}, t)$

Beam Centroid $X = \langle x \rangle_{\perp}$ $X' = \langle x' \rangle_{\perp}$ Phase-Space: $Y = \langle y \rangle_{\perp}$ $Y' = \langle y' \rangle_{\perp}$

Beam Emittance:

 $\varepsilon_y = 4 \left[\langle y^2 \rangle_\perp \langle y'^2 \rangle_\perp - \langle yy' \rangle_\perp^2 \right]^{1/2}$ SM Lund, USPAS, 2016
