

# Opportunities For In-Beam Spectroscopy

- Introduction (context)
- A few physics examples
  - Discovery at the driplines
  - Ca isotopes as archetype
  - Octupole collectivity and the EDM
  - rp-process and astrophysics
- Conclusions and remarks
- Acknowledgements

# Intellectual Challenges

The 2012 National Research Council (NRC) decadal survey on nuclear physics posed four over-arching questions that frame the intellectual challenges of the field.

- *How does subatomic matter organize itself and what phenomena emerge?*
- *How does visible matter come into being and how does it evolve?*
- *Are the fundamental interactions that are basic to the structure of matter fully understood?*
- *How can the knowledge and technological progress provided by nuclear physics best be used to benefit society?*

In-beam spectroscopy is essential to answering all these questions!

# Addressing the Challenges

## 1) Rare Isotope Beams

FRIB and the production of the most exotic nuclei

## 2) State-of-the-art instrumentation

Stable and RIB experiments  
(ATLAS, NSCL, CARIBU, FRIB...)

# In-Beam Neutron Spectroscopy: Beyond the Driplines

Evolution of nuclear shell structure at extreme neutron to proton ratios.

Study of nuclei beyond the neutron drip line

Correlations in two neutron decays.

New phenomena in exotic nuclei.

In the future MoNA will be combined with the High Rigidity Spectrometer (HRS)

# Beyond the Driplines

**Discovery of two-neutron unbound  $^{26}\text{O}$**   
 $^{26}\text{O}$  g.s. resonance energy < 200 keV

Lunderberg et al. PRL 108 (2012) 142503

## Evidence for two-neutron radioactivity

$t_{1/2} \sim 4.5$  ps for 2n decay of  $^{26}\text{O}$

Kohley et al. PRL 110 (2013) 152501

# In-Beam Gamma-Ray Spectroscopy: GRETA

## THE GAMMA-RAY ENERGY TRACKING ARRAY GRETA

Input to the 2014 Nuclear Astrophysics and Low Energy Physics Town Meeting  
(Texas A&M University, August 21-23, 2014)

- $\gamma$ -ray tracking array with unmatched position resolution for precise Doppler reconstruction of  $\gamma$  rays emitted in flight
- High efficiency allows furthest scientific reach
- $4\pi$  coverage for angular distributions, correlations, polarization, g-factors (RIV), and lifetime measurements
- Concept proven with highly successful GRETINA science campaigns
- Community endorsed (NSAC 2002, 2007 LRPs, and FRIB SAC).

GRETA can be used for all  $\gamma$ -ray tagged reactions with fast and reaccelerated beams (Coulomb excitation at all energies, transfer, knockout, charge exchange, fragmentation, inelastic hadronic scattering, ... **coupled to separators, charged particle arrays, neutron detector arrays, ...**)

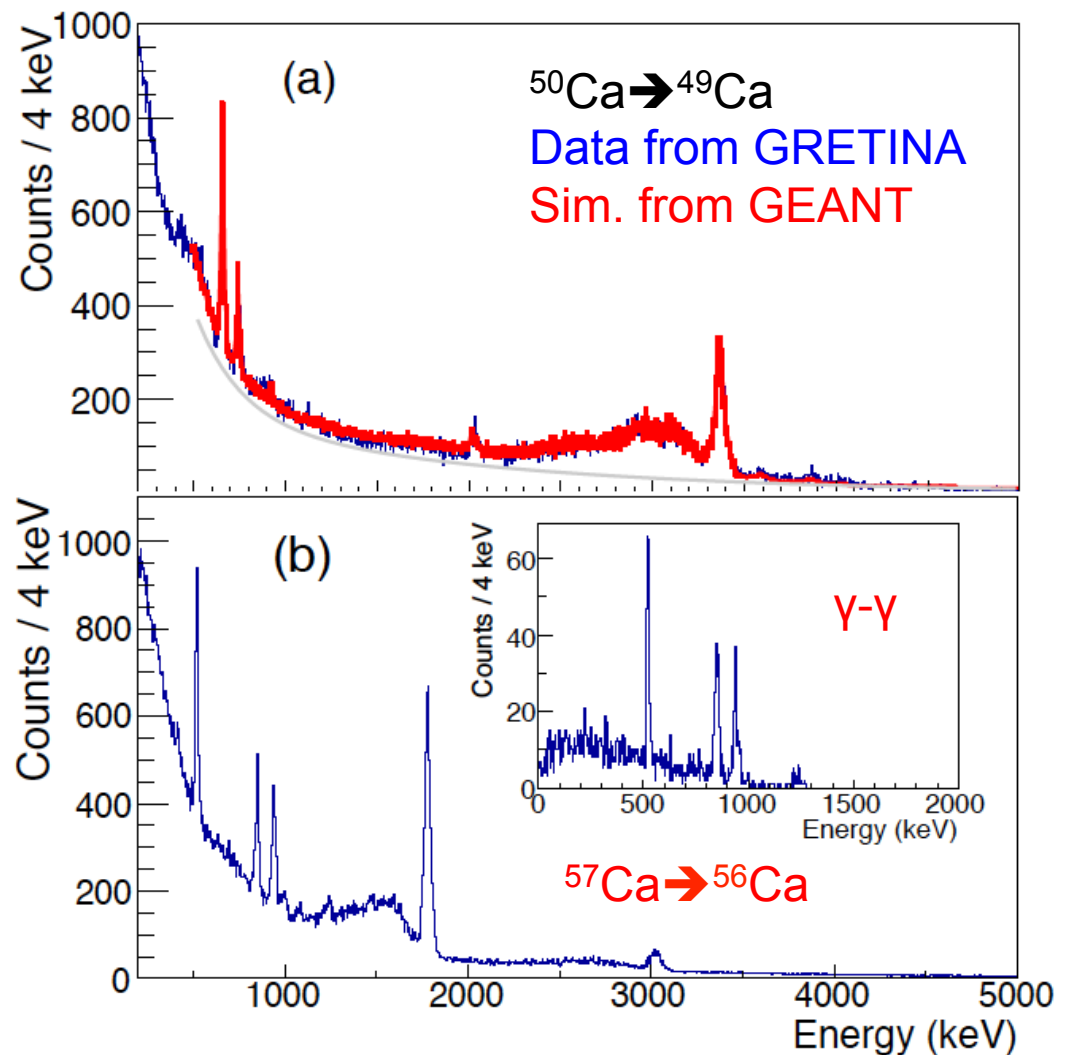

Maximizes the science reach at existing and future facilities. e.g. ANL, NSCL and FRIB.

# Ca Isotopes: Archetype of Structural Evolution

Dramatic example of single-particle evolution (due to spin-isospin component of nn-interaction) resulting in new subshell structure at N=32,34

Microscopic calculations suggest particular sensitivity to inclusion of 3N forces

Detailed spectroscopy using one-nucleon knockout can be extended to a least  $^{56}\text{Ca}$  with GRETA at FRIB

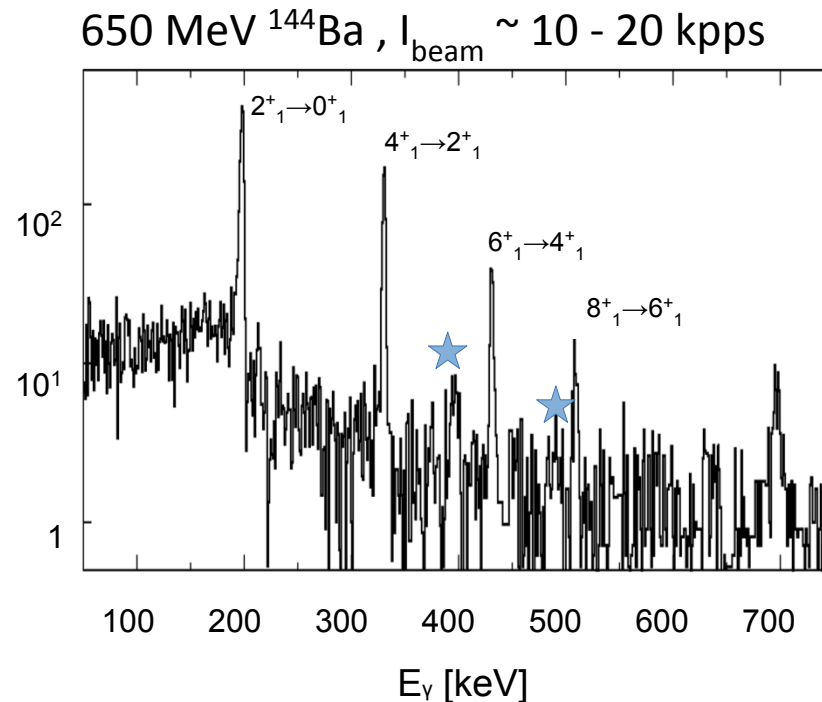

# Spectroscopy of $^{60}\text{Ca}$

- The structure around  $^{60}\text{Ca}$  informs the location of the dripline in  $Z=20$  chain
- Nuclear models, including ab-initio calculations, use the Ca chain as a test bed for the most modern interactions
- Spectroscopy of this key nucleus:  $^9\text{Be}(^{61}\text{Sc}, ^{60}\text{Ca}+\gamma)\text{X}$  at FRIB with fast-beam knockout possible
- The efficiency gain with GRETA over GRETINA is a game changer

Simulation assumes rates at FRIB, performance parameters of proposed HRS, and GRETA for in-beam spectroscopy

# New Regions of Octupoles

- Reaccelerated CARIBU beam
- Goal: measure  $B(E1)$  and  $B(E3)$  matrix elements for transitions decaying from octupole to yrast band labeled with ★

One of the first measurements with GRETINA at ATLAS.

M. Albers *et al.*, (2014) (ANL, LLNL, Rochester, LBNL, NSCL, FSU)

# Octupoles and the EDM

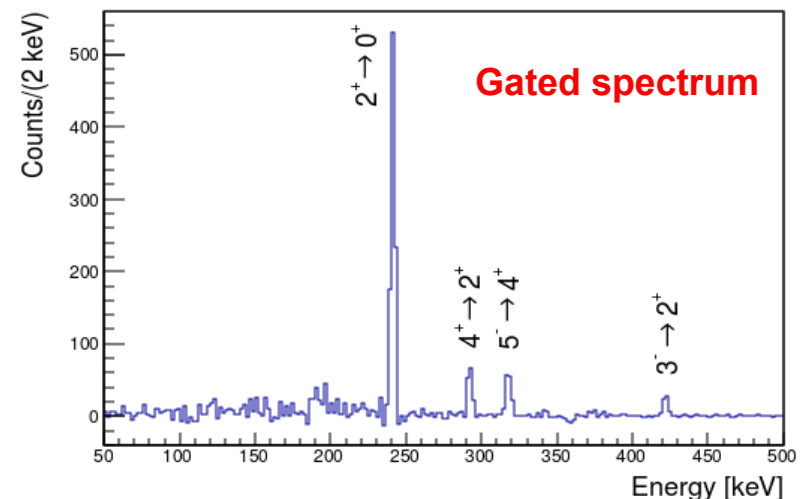

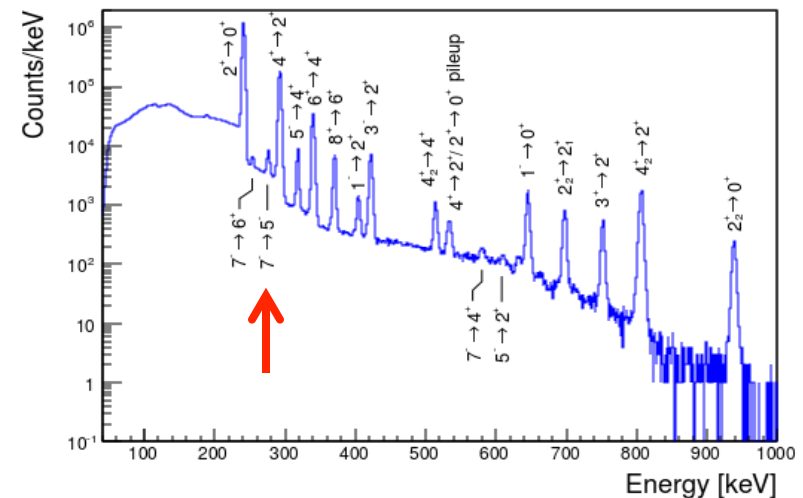

Search for permanent Electric Dipole Moment (EDM) indicating time-reversal (T) or charge-parity (CP) violation due to physics beyond the Standard Model

Nuclear octupole deformation can “amplify” the atomic EDM by several orders-of-magnitude (through Schiff moment induced contribution)

Likely candidates for EDM experiments at FRIB lie in the Ra, Rn, Pa region.

Must characterize the octupole collectivity through high statistics, multi-step, Coulomb excitation

GRETA+CHICO2 Simulation for  $^{220}\text{Ra}$

# Astrophysics Example

Kontos,<sup>1,2</sup> I.-Y. Lee,<sup>6</sup> A. Lemasson,<sup>1</sup> E. Lunderberg,<sup>1,5</sup> Y. Maeda,<sup>10</sup> M. Matos,<sup>11</sup> Z. Meisel,<sup>1,2,5</sup> S. Noji,<sup>1</sup> F. M. Nunes,<sup>1,5</sup> A. Nystrom,<sup>3</sup> G. Perdikakis,<sup>12,1,2</sup> J. Pereira,<sup>1,2</sup> S. J. Quinn,<sup>1,2,5</sup> F. Recchia,<sup>1</sup> H. Schatz,<sup>1,2,5</sup> M. Scott,<sup>1,2,5</sup> K. Siegl,<sup>3</sup> A. Simon,<sup>1,2,8</sup> M. Smith,<sup>3</sup> A. Spyrou,<sup>1,2,5</sup> J. Stevens,<sup>1,2,5</sup> S. R. Stroberg,<sup>1,5</sup> D. Weisshaar,<sup>1</sup> J. Wheeler,<sup>1,2,5</sup> K. Wimmer,<sup>12,1</sup> and R. G. T. Zegers<sup>1,2,5</sup>

The  $^{57}\text{Cu}(p,\gamma)^{58}\text{Zn}$  stellar reaction rate has a significant effect in the light-curve emitted in X-ray bursts.  $^{58}\text{Zn}$  excitation energies are not known experimentally.

The effective lifetime of  $^{56}\text{Ni}$  determines the amount of  $A=56$  material in the neutron star crust.

$^{57}\text{Cu}$  beam  $\sim 3 \cdot 10^4$  pps produced from stable  $^{58}\text{Ni}$  @160 MeV/u on 225mg/cm<sup>2</sup> CD<sub>2</sub> target

### Reaction rate dominated by $2^+$ resonances

# $^{58}\text{Zn}$ Spectroscopy (Completes Isospin Triplet)

With FRIB and GRETA+S800 (or HRS) we will be able to investigate key rp-process nuclei and consequences of their structure on reaction rates.

# Conclusion

## Intellectual challenges from NRC Decadal Study

How does subatomic matter organize itself and what phenomena emerge?	How did visible matter come into being and how does it evolve?	Are fundamental interactions that are basic to the structure of matter fully understood?	How can the knowledge and technological progress provided by nuclear physics best be used to benefit society?
--	--	--	---

## Overarching questions from NSAC Long Range Plan

What is the nature of the nuclear force that binds protons and neutrons into stable nuclei and rare isotopes?  What is the origin of simple patterns in complex nuclei?	What is the nature of neutron stars and dense nuclear matter?  What is the origin of the elements in the cosmos?  What are the nuclear reactions that drive stars and stellar explosions?	Why is there now more matter than antimatter in the universe?	What are new applications of isotopes to meet the needs of society?
---	---	---	---

## Science drivers (thrusts) from NRC RISAC

Nuclear Structure	Nuclear Astrophysics	Tests of Fundamental Symmetries	Applications of Isotopes
-------------------	----------------------	---------------------------------	--------------------------

## Overarching questions are answered by rare isotope research

### 17 Benchmarks from NSAC RIB TF measure capability to perform rare-isotope research

1. Shell structure 2. Superheavies 3. Skins 4. Pairing 5. Symmetries 13. Limits of stability 14. Weakly bound nuclei 15. Mass surface	6. Equation of State (EOS) 7. r-Process 8. $^{15}\text{O}(\alpha, \gamma)$ 9. $^{59}\text{Fe}$ s-process 15. Mass surface 16. rp-Process 17. Weak interactions	12. Atomic electric dipole moment 15. --	--	--	--------------------------------

In-beam spectroscopy is essential to this entire field!

# Suggested Text Needed in LRP

For **FRIB**, we need the **highest** recommendation:

*“We recommend completion of the Facility for Rare Isotope Beams (FRIB), a world-leading facility for the study of nuclear structure, reactions, and astrophysics...”*

For **GRETA**, we must build on the endorsements in the 2002 and 2007 plans.

*“The detection of  $\gamma$ -ray emissions from excited nuclei plays a vital and ubiquitous role in nuclear science. The physics justification for a  $4\pi$  tracking array is extremely compelling, spanning a wide range of fundamental questions in nuclear structure, nuclear astrophysics, and weak interactions.”* - 2002 NSAC Long Range Plan

*“Construction of GRETA should begin immediately upon the successful completion of the GRETA array”* - 2007 NSAC Long Range Plan

It must feature **clearly and prominently as an initiative**:

*“Construction of GRETA should begin immediately. This is essential if the full scientific potential of existing and future facilities, especially FRIB, is to be fulfilled...”*

Many thanks to:

Mike Carpenter, Heather Crawford, Paul Fallon,  
Alexandra Gade, Augusto Macchiavelli,  
Artemis Spyrou, Shaofei Zhu

and to you...

# IN-BEAM SPECTROSCOPY AT THE LIMITS — $^{32,34}\text{Mg}$

Characterizing rotational structures in the Island of Inversion  $^{32,34}\text{Mg}$  nuclei will provide insight into:

- extent and stability of deformation
- evolution of shape with spin and binding
- nucleon-core coupling

# IN-BEAM SPECTROSCOPY AT THE LIMITS – $^{40}\text{Mg}$

A complete picture of changing shape in the Mg isotopes will require quantifying the degree of deformation, and mapping the evolution of nucleon single-particle states.

Nucleon knockout reactions can probe single-particle occupancies along the isotopic chain – but at the limits, the rates will be low, detailed spectroscopy will be demanding.

Coulomb excitation can provide quantification on the extent of collectivity.

$^{40}\text{Mg}$  Coulex, with a predicted 9 pps at FRIB will require high-efficiency gamma-spectroscopy, with the resolution to observe a peak above background.

# WHAT DO WE NEED?

Neutron-rich Mg at FRIB  
( $\sim 200\text{MeV/u}$ ) will be  
among the **most**  
**demanding** beams in terms  
of  $B\rho \rightarrow {}^{40}\text{Mg} \sim 7\text{ Tm}$

→ HRS is critical  
requirement for  
spectroscopy with fast  
beams at FRIB

Spectroscopy with rates on  
the order of 1 pps, or <  
0.1% branches require  
**high-efficiency** detectors;  
complex level schemes  
**demand resolution**

→ GRETA will be a  
cornerstone for fast-beam  
physics

# Unsafe Coulex to probe medium to high spin states in neutron rich nuclei

**Premise:** Identification of high-spins states which are inaccessible from beta-dacay or reaction studies provide a more complete knowledge base for understanding the nuclear structure not only at high-angular momentum but near the ground state as well.

*Low Energy Town Meeting  
Nuclear Structure and Reactions  
August 22, 2014  
Michael P. Carpenter*

# Accessing High-Spins of Neutron Rich Nuclides with Deep Inelastic and Other More Exotic Reactions

- Self supporting  $^{26}\text{Mg}$  target,  $0.973 \text{ mg/cm}^2$  thick
- $^{48}\text{Ca}$  beam @ 320 MeV (>200% above Coulomb barrier)
- Intensity  $\sim 200 \text{ pA}$
- $^{26}\text{Mg}(^{48}\text{Ca}, 7n4p)^{63}\text{Ni}$  – 2% of  $\sigma_{\text{tot}}$
- Selectivity made using focal plane detectors
- 3 high-spin deformed bands observed – shape coexistence
- Previously  $^{63}\text{Ni}$  only identified up to  $13/2^+$  state
- Also new studies of  $^{61}\text{Co}$  and  $^{62-65}\text{Ni}$ .

M. Albers, S.Zhu *et al.*, PRC 88, 054314 (2013)

# Will these techniques work with RIB's.

- Short Answer : Yes ... But ....
- Fusion-like reactions will have higher probabilities of neutron evaporation as compound systems become more neutron-rich – limits the accessibility to neutron rich isotopes
- Deep-Inelastic Reactions are in principle but are not very selective – i.e. reaction channels can encompass hundreds of nuclei and this can be a show-stopper using RIB's with reduced intensities (compare  $10^6$  with  $10^{10}$ )
- But – With FRIB and CARIBU, we have access to reaccelerated neutron rich RIBs which offers the opportunity for direct excitation of the beam *i.e.* Unsafe Coulex – excitation of beam using where  $E_{\text{beam}} \sim 5\text{-}6 \text{ MeV/u}$ .

**LARGEST and DOMINANT CROSS-SECTION is DIRECT EXCITATION OF BEAM**

## Here is an example (also see Partha's Talk)

# What is Needed?

- High Efficiency Gamma-ray Spectrometer – **GRETA**
- High Efficiency and Highly pixelated particle counter at target – **SUPER CHICO**
- Reaccelerated RIB's at  $\sim 5\text{-}6\text{ MeV/u}$
- Intensities for GRETA
  - $10^2 - 10^3 - \gamma\text{-rays singles}$
  - $10^4 > \gamma\text{-ray coincidences}$

These studies can begin now - **CARIBU, REA3, ISAC2**

**1-phonon octupole state firmly established**  
**2-phonon octupole candidate**

**Unsafe Coulx of  $^{142}\text{Ba}$  at  $\sim 110\%$  over Coulomb could confirm 2-phonon character of state though identification of states on top of candidate state.**

**Requires Gammasphere or Gretina and  $I > 10^5$**

S. Zhu et al., to be published - Gammasphere

# Nuclear Structure and Reactions with MoNA-LISA

Sharon Stephenson

Gettysburg  
COLLEGE

2003: MoNA modules assembled by undergraduate students at NSCL

2004: Sweeper magnet built by FSU/NHMFL installed at NSCL

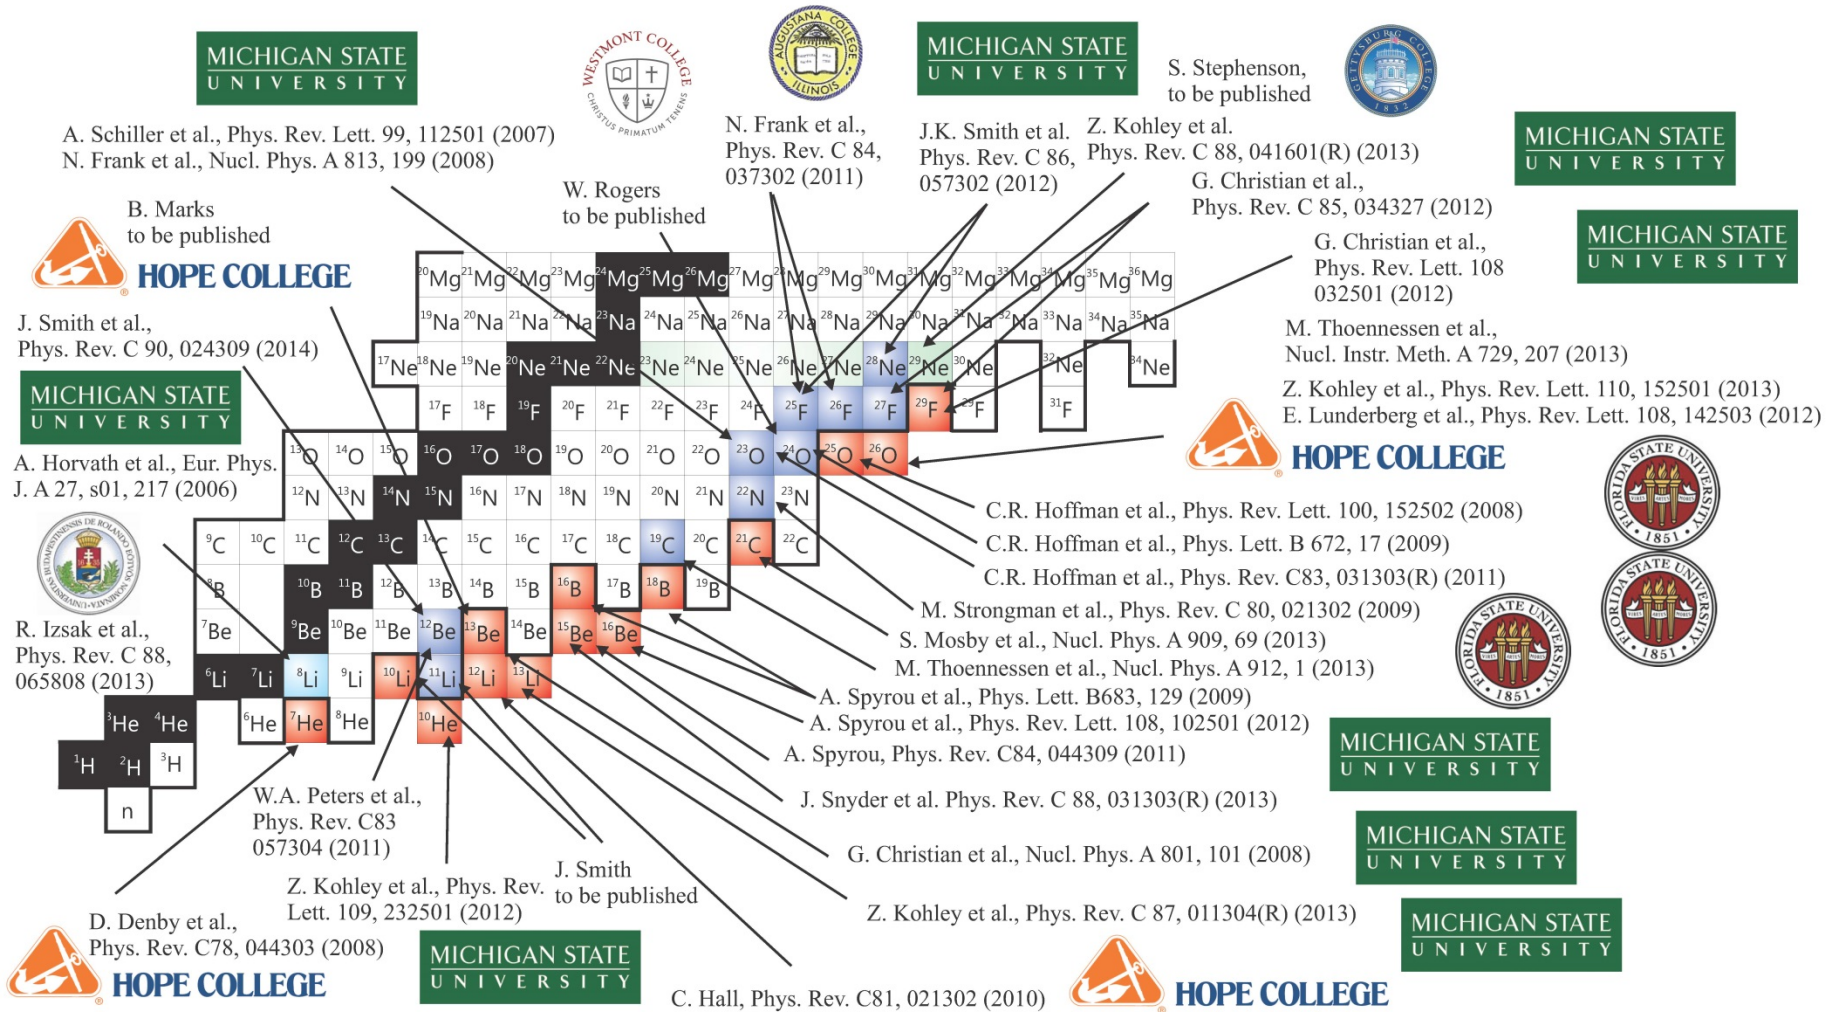

2011: LISA completed

2013: Hodoscope built by Augustana/NSCL installed at NSCL

2014: Liquid D target, development of segmented target

# Physics with 10 years of MoNA

# Highlights

- Discovery of 6 new isotopes:  $^{15}\text{Be}$ ,  $^{16}\text{Be}$ ,  $^{18}\text{B}$ ,  $^{25}\text{O}$ ,  $^{26}\text{O}$ ,  $^{28}\text{F}$
- First experimental determination of the  $N=16$  shell closure in  $^{24}\text{O}$
- Observation of direct two-neutron emission in  $^{16}\text{Be}$
- First indication of two-neutron radioactivity in  $^{26}\text{O}$
- In addition to nuclear structure experiments MoNA has been used to:
  - measure the Coulomb dissociation of  $^8\text{Li}$  to study the astrophysical relevant reaction  $^7\text{Li}(n,\gamma)$
  - exploit neutron-rich radioactive beams to constrain the symmetry energy
  - determine the mass and excitation energy of precursor intermediate products in projectile fragmentation reactions

# MoNA-LISA with FRIB

- Until now the nuclear structure experiments explored the transition between the *p* and *sd* shell and the evolution within in the *sd*-shell
- FRIB offers the opportunity to expand these studies into the *pf*-shell

<sup>27</sup> Al	<sup>28</sup> Al	<sup>29</sup> Al	<sup>30</sup> Al	<sup>31</sup> Al	<sup>32</sup> Al	<sup>33</sup> Al	<sup>34</sup> Al	<sup>35</sup> Al	<sup>36</sup> Al	<sup>37</sup> Al	<sup>38</sup> Al	<sup>39</sup> Al	<sup>40</sup> Al	<sup>41</sup> Al	<sup>42</sup> Al
<sup>26</sup> Mg	<sup>27</sup> Mg	<sup>28</sup> Mg	<sup>29</sup> Mg	<sup>30</sup> Mg	<sup>31</sup> Mg	<sup>32</sup> Mg	<sup>33</sup> Mg	<sup>34</sup> Mg	<sup>35</sup> Mg	<sup>36</sup> Mg	<sup>37</sup> Mg	<sup>38</sup> Mg		<sup>40</sup> Mg

<sup>23</sup> F	<sup>24</sup> F	<sup>25</sup> F	<sup>26</sup> F	<sup>27</sup> F		<sup>29</sup> F		<sup>31</sup> F							
<sup>22</sup> O	<sup>23</sup> O	<sup>24</sup> O													
<sup>21</sup> N	<sup>22</sup> N	<sup>23</sup> N													
<sup>20</sup> C		<sup>22</sup> C													

 Ground states that could be measured with FRIB that are not accessible at the NSCL

 Nuclei with  $S_n < 3$  MeV, possible excited states to be measured at FRIB

# High Rigidity Spectrometer HRS

- The 288 detectors of the two arrays are sufficient to cover the needed energy and angular range
- The main limitation is the small vertical gap of the Sweeper magnet (14cm)
- A large gap dipole as proposed with the HRS is required to explore the full capabilities of FRIB and MoNA-LISA

# Conclusion

- MoNA-LISA is the ideal detector to explore the evolution of the *pf*-shell at and beyond the dripline
- In addition the MoNA-LISA/HRS setup can study reaction mechanisms of neutron rich beams (for example to understand the projectile fragmentation process and constrain the symmetry energy)
- MoNA-LISA is ready to go -- the construction of the HRS is essential

- The single particle energies within the  $f_{7/2+}$  orbit change very little with increasing neutron number
- The separation energies stay almost constant
- Potential for several neutron unbound isotopes with low decay energy

B.A. Brown, Prog. Part. Nucl. Phys. 47 (2001) 517

# Four-neutron emitter

- The FRDM predicts  $^{38}\text{Ne}$  and  $^{44}\text{Mg}$  to be direct four neutron emitters
- They are bound with respect to 1-, 2-, and 3-neutron emission but unbound with respect 4-neutron emission

**Conclusion:** Isotopes beyond the neutron dripline within the  $pf$ -shell offer a large discovery potential which can be explored with FRIB, MoNA-LISA and the HRS.

# Hypernuclear Physics

- Baryonic interactions and many body baryonic system
  - *Primary effort of nuclear physics*
- New flavor in SU(3):  $YN$  and  $YY$
- Important linkage to Astrophysics: neutron stars, hyperon matter, ...
- Short range baryonic interactions:  $\Lambda N - \Lambda N$
- Baryonic structure of the nuclear medium probed by  $\Lambda$
- $\Lambda$ - $\Sigma$  coupling: Charge Symmetry Breaking (CSB) and  $3BF(\Lambda NN)$
- Past: Hypernuclear Program at JLab (a hadron physics facility):
  - Proven the feasibility and technique of electro-production
  - Achieved the highest possible precision in mass spectroscopy  
( $\delta E \sim 500$  keV FWHM and  $\delta B_{\Lambda} < \pm 100$  keV) – Unique
  - Studied the spectroscopy of a sequence of  $\Lambda$ -hypernuclei:  
 ${}^7_{\Lambda}\text{He}$ ,  ${}^9_{\Lambda}\text{Li}$ ,  ${}^{10}_{\Lambda}\text{Be}$ ,  ${}^{12}_{\Lambda}\text{B}$ ,  ${}^{16}_{\Lambda}\text{N}$ ,  ${}^{28}_{\Lambda}\text{Al}$ , and  ${}^{52}_{\Lambda}\text{V}$  – the only new results exist in the past decade and near future

# Example: Precision $^{12}_{\Lambda}\text{B}$ Spectroscopy and Shell Model

$^{12}\text{C}(e, e'\text{K}^+)^{12}_{\Lambda}\text{B}$

$S_{\Lambda} \otimes ^{11}\text{B}$

$S_{\Lambda} \otimes ^{11}\text{B}$  (SD shell)

$^{11}\text{B}(5/2^+; 11.6) \otimes S_{\Lambda}$  #7 11.75  $\pm$  0.04

$^{11}\text{B}(3/2^+; 7.978) \otimes S_{\Lambda}$  #4 8.86  $\pm$  0.07

$P_{\Lambda} \otimes ^{11}\text{B}$

# Future: Program on Hypernuclear Spectroscopy

## Technical Features:

- High precision and high yield  
( $\delta E \sim 600$  keV FWHM and  $\delta B_A \sim \pm 50$  keV)
- “Free” of accidental background
- All major equipment already exist

## Physics:

- Few body  
*Charge Symmetry Breaking (CSB) in  $\Lambda N$  interactions*
- Medium heavy hypernuclei  
*LS force; shell model on baryonic many-body system; structure or deformation of the core nuclei probed by  $\Lambda$*
- Heavy hypernuclei ( $A \sim 200$ ) – precise  $B_A$  and level spacing  
*Importance of  $3B/4B$  forces; many body vs QCD descriptions*
- Decay pion spectroscopy (Ground state of light hypernuclei;  $\delta E \sim 130$  keV &  $\delta B_A \sim \pm 20$  keV)  
 *$\Lambda N$  interactions; CSB;  $\Lambda$ - $\Sigma$  coupling; drip line hypernuclei ( ${}^6_\Lambda H$ )*

# Hypernuclear Physics Programs and Facilities

JLAB program plays a unique role in the global effort on the strangeness nuclear physics

## JLAB

### Electroproduction

- $\Lambda$  hypernuclei (few-body to heavy)
- High precision mass spectroscopy and precise  $B_\Lambda$  determination
- *The only facility at the moment and near future*

## J-PARC

### Hadronic production

- $\gamma$  spectroscopy of  $\Lambda$  hypernuclei
- $S = -2$   $\Xi$  and  $\Lambda\Lambda$  hypernuclei
- Kaonic nuclei ( $K^-NNN$ , ...)

## MAMI

### Decay pion spectroscopy

- Ground state of light  $\Lambda$  hypernuclei
- Precise  $B_\Lambda$  on the ground state

## PANDA @ Fair

### Heavy Ion Collision

- Multi-strangeness
- Extreme p and n numbers
- Anti-hypernuclei
- Charm-hypernuclei

# NUCLEI AT THE EXTREMES: AT THE LIMITS OF ANGULAR MOMENTUM

## Increasing Angular Momentum and Excitation Energy:

This is an excellent way to investigate nuclear structure. Remember these studies are ultra-sensitive to what the intruder shells are doing!

## RECENT ACHIEVEMENTS

Here we list several key achievements made since the last Long Range Plan. They have produced new insights into nuclear structure and nuclear astrophysics, and they highlight the increasingly strong research overlap between the physics of nuclei and nuclear astrophysics.

# 2007 LRP 8 topics chosen

### The physics and chemistry of superheavy elements.

We continue to move closer to the predicted super-heavy island of stability. Synthesis of superheavy elements up to  $Z = 118$  in fusion reactions was reported, and the chemical properties of elements up to  $Z = 112$  have been studied. In elements with  $Z = 100$ – $102$ , energies of isomeric states provided new probes of higher-lying shells, the very shells governing the stability of superheavy nuclei.

- **Collective behavior and symmetries.** Measurements of nuclei in shape transitional regions, near  $N = 90$  and elsewhere, led to an interpretation in terms of quantum phase transitional behavior between different symmetries. A new class of many-body symmetries describing nuclei at the phase transitional point was developed. Pushing the limit of extreme nuclear spin, rotational behavior was discovered at high spins in  $^{157,158}\text{Er}$ , beyond the angular momenta at which many rotational bands terminate, challenging microscopic descriptions of collectivity.

# Evolution of Gamma-Ray Spectroscopy and $^{158}\text{Er}$

(NRC/Nat. Acad. Sci. Decadal Report June 2012, p 49  
Nuclear Physics: The Heart of Matter)  
NEW INSTRUMENTATION = NEW PHYSICS!

After decades of trying to go beyond Band Termination ( $I \sim 50$ )

The return of collectivity at ultra-high spin in  $^{158}\text{Er}$   
(Paul *et al.*, Phys.Rev.Lett. 98, 012501, 2007)

The Excitement has Continued and Increased since then!

Quadrupole moment measurements a ***complete surprise!!***  
(Wang *et al.*, Phys. Lett. B 702, 127, 2011)

[FSU, Daresbury, Liverpool, ANL, LBNL, USNA, UTK, ND, iTHEMBA, Lund]

Lots of theoretical interest: Robust triaxial shapes, tilted-axis cranking, large deformations, spins close to fission limit

Shi *et al.*, PRL 108, 09250, 2012

Kardan *et al.*, PRC 86, 014309, 2012

Afanasjev, Shi, Nazarewicz, PRC 86, 031304 (R) (2012)

If the theoretical spin assignments of Fig. 4 turned out to be correct, the experimental band 1 in  $^{158}\text{Er}$  would be the the highest spin structure ever observed. The current study stresses the need for more precise measurements of  $Q_t$  and reliable estimates of spins in these bands.

# THE FUTURE AND RESOURCES NEEDED

- New exotic shape minimum at ultra-high spins ( $I \sim 70$ ).
- Fascinating spectroscopy at the limits awaits us.
- To fix the spins and excitation energies, and do complete spectroscopy **WE NEED GRETA!**
- Also stable beams from ATLAS at ANL.
- And targets from CATS (Nat. Cen. Accel. Targets. Sci.)

# Study of $^{218}\text{U}$ : proton shell closure above $^{208}\text{Pb}$

Near-term goal: Observe the low-spin states in this  $N = 126$  nucleus at the upper end of the  $\pi h_{9/2}$  shell

Scenarios:

- $^{208}\text{Pb}$ -like behavior ( $2^+$ ,  $3^-$  change position)
- Seniority-type sequence like  $^{216}\text{Th}$  ( $8^+$  isomer)

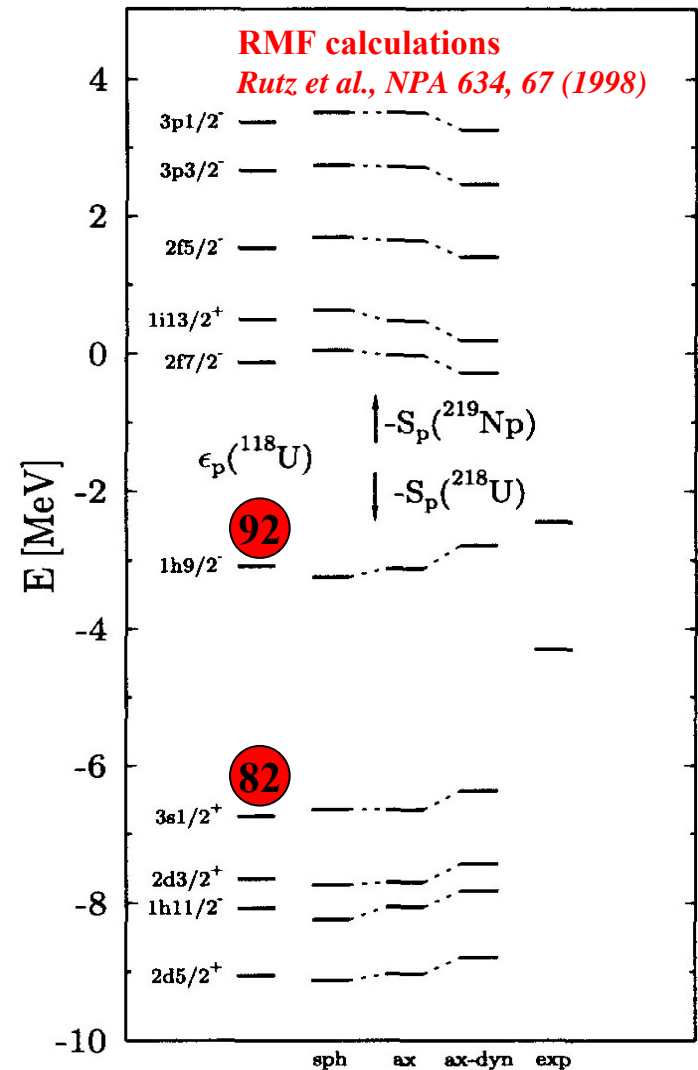

Options for experiments:

1. Fusion-evaporation ( $\sigma_{\text{ER}} \gtrsim 1 \text{ nb}$ ) RDT run  
Gretina/Gammasphere + AGFA
2. Pre-FRIB  $^{218}\text{U}$  Coulex run  
Gretina + particle detector + S800

Far-term goal: Measure  $B(E2)$  and  $B(E3)$  (or  $B[E1]$ )  
FRIB Coulex experiment

**Factors that likely affect the  $Z=92$  gap:**

- octupole correlations: alter  $\pi 2f_{7/2}$  level
- proton pair scattering

# What if $2^+$ and $3^-$ change position at the sub-shell closure?

**No E1/E3 competition (not like in  $^{216}\text{Th}$ )!**

**Possible change of decay pattern for even-spin states!**

**Prompt spectroscopy gains in importance over delayed spectroscopy!**

Impact of  $3^-$  state: description of nearby odd-mass nuclei (particle-core coupling).

## Outline of $^{218}\text{U}$ RDT experiment

Use Leppanen's reaction\*:  $^{40}\text{Ar} + ^{182}\text{W} \rightarrow ^{218}\text{U} + 4\text{n}$  ;  $E_{\text{lab}}=184$  MeV (mid-tgt.).

$\sigma_{\text{ER}}=1.2$  nb; do excitation function.

Tag on g.s.  $\alpha$  decay:  $t_{1/2} = 6$  ms.

**Need to run fast:**  $\geq 50$  pA; need GRETINA or Digital Gammasphere.

Educated guess for AGFA transmission:  $\geq 50\%$ ; experiment is doable.

ToF=890 ns (4.8 m); this helps if isomeric transitions are present (if  $^{216}\text{Th}$ -like).

But, an additional Ge setup at the focal-plane is desirable.

**However, the main objective is to determine the  $2^+$  and  $3^-$  states!**

---

\**Leppanen et al. PRC 75, 054307 (2007)*

Thanks for your attention!

# g Factors

sensitive test of wavefunction components

Predictions for B(E2) and Q are often similar but not for g

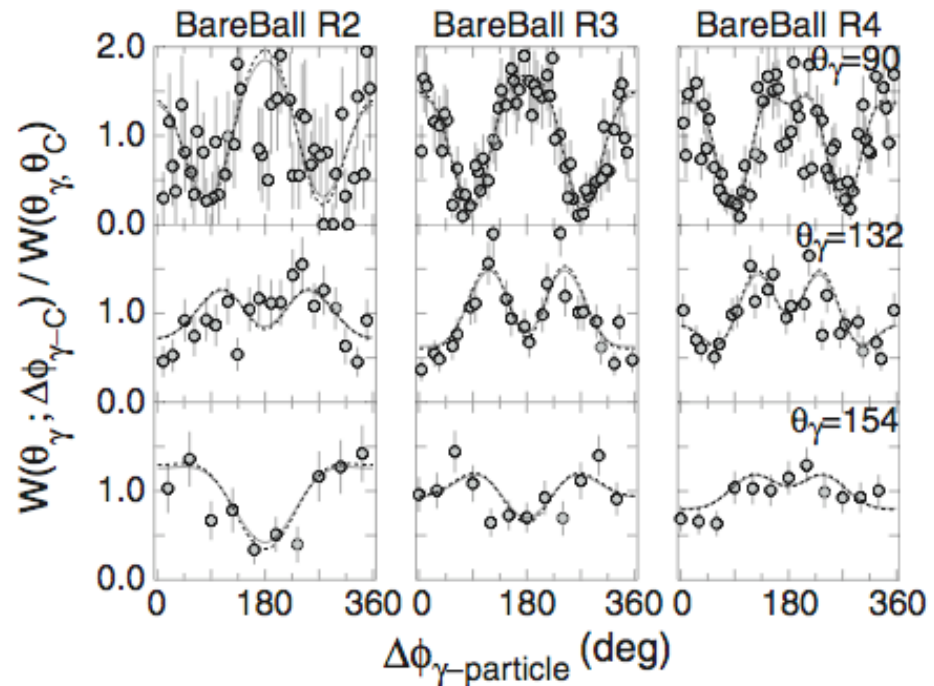

g-factor by RIV can be done using Coulex with B(E2) and Q measurements

# Safe Coulex at Back C.M. Angles

Can extract all three E&M moments at backward c.m. angles

B & Q from particle- $\gamma$  yields per  $\theta_{\text{particle}}$   
g from  $\Delta\phi$  particle- $\gamma$  ang. dist. (RIV)

# \*Safe Coulex At and Near **Shell Closures**

## Primary Facility Requirements:

1-3 MeV/u (~Pure) Beams  
Small Beam Spot  
 $4\pi$   $\gamma$ -ray detector (for  $10^{3-5}$  pps)  
 $4\pi$  or  $2\pi$  (inv kin) particle detector

Doubly Magic?  
New Frontier!

Explore p-n interactions!

ReA3(including N-rich Ca)  
CARIBU

\*  $^{13}\text{C}$  target would allow Coulex and simultaneous sub-barrier 1N transfer for single-neutron ANC's and  $\tau$  (DSAM)

Measure Complete E&M Set:  
 $B(E2; 2_1)$  - Coherent Motion  
 $Q(2_1)$  - Shape  
 $|g(2_1)|$  - Currents / Orbits

# Near and sub-barrier fusion as a probe of nuclear structure

Neutron-rich and proton-rich nuclei  
probe intrinsically different environments  
due to the Coulomb barrier

Very neutron-rich nuclei:

$N/Z \approx 2 - 2.5$ ,  $S_n < 1$  MeV

- Diffuseness of neutron distribution (neutron skins & halos)
- More states near the Fermi surface (level density)
- Breakdown of the single-particle description (Clustering at low  $\rho$ )
- Redefinition or disappearance of magic numbers

Sub-barrier fusion is particularly sensitive to the tail of the nuclear matter distribution, hence provides a good probe of the neutron and proton distributions.

Measuring fusion for an isotopic chain of projectile nuclei one can sensitively examine the dependence of fusion on the isospin degree-of-freedom.

Comparison of high quality, experimental data with  
microscopic models provides information about the  
density distributions of neutrons and protons.

A.S. Umar et al., PRC 85 055801 (2012)

# Present status of sub-barrier fusion with n-rich light nuclei

Measuring the fusion cross-section near and below the barrier with low intensity beams

Beam intensity:  $10^4 - 10^5$  pps

- Direct measurement of evaporation residues by Energy-TOF allows determination of the fusion cross-section to the 2-3 mb level (one order of magnitude lower than prior measurements!)
- It is now possible to perform microscopic calculations that include pairing (density constrained TDHF), providing a relevant comparison for the experimental data.
- The experimental data manifest a significant enhancement in the sub-barrier region. Can be interpreted as:
  - Larger tunneling probability, weaker barrier/deviation from inverted parabolic shape (sensitivity to n/p density distributions)
  - Pairing configuration changes as reaction dynamics proceeds

Theoretical support:  
S. Umar/V. Oberacker, Vanderbilt University

# Future Plans and Challenges

1) Establish a high quality, **systematic set of sub-barrier fusion excitation functions for neutron-rich nuclei in this mass range.** [e.g.  $^{19,20,22}\text{O}$  beams;  $^{12}\text{C}$ ,  $^{18}\text{O}$  targets]

- **Stringent test of microscopic models (both statics and dynamics)**
- **Astrophysical implications : Constrain neutron star crust models**

Challenge: Availability of low energy, neutron-rich beams with sufficient intensity

Challenge: Improved detector systems to reduce sensitivity to background

2) Utilize (measure) the multiplicities, kinetic energies, and angular distributions of the emitted particles (proton, alpha, and neutron) to **examine the decay characteristics of the compound nuclei.**

- **Access information on the level density of dilute nuclear matter**
- **Clustering effects in low density nuclear matter at low excitation**

Challenge: Efficient measurement of low energy emitted particles, **including neutrons** in coincidence with the evaporation residue

3) **Improve microscopic models** (e.g. to allow pairing to evolve as the reaction dynamics proceeds)

**Grand Challenge Theoretically: develop TDHFB code on 3D lattice for nuclear reactions**

# Investigation of Deep Inelastic, Multi-nucleon Transfer Reactions for the Creation of Super- and Hyper-heavy Elements

S. Wuenschel, J.B. Natowitz, K. Hagel, M. Barbui, G. Giuliani, E.J. Kim, N. Blando, H. Zheng, S. Kowalski, K. Schmidt, Z. Majka, Z. Sosin, A. Wieloch.

- This experiment
  - TAMU K500
  - 7.5 MeV/A  $^{197}\text{Au} + ^{232}\text{Th}$
  - Thick target (11 mg/cm<sup>2</sup>)
  - Observe alpha decays

**Alternative methods may provide favorable cross sections for heavy element production.**

- Multi-nucleon transfer
- Asymmetric fission of heavier, transient systems

**Observing alpha particles emitted from reaction residues**

# The Initial Experiment

# The Initial Experiment

## PASSIVE CATCHER

# The Initial Experiment

PASSIVE CATCHER

Time distributions gated on alpha energy 100ms on, 100 ms off. Half-lives determined from fitting beam on and beam off data with three components

# Outlook

Active Catcher

- Separate alpha decays from ternary fission alpha particles
- Build decay chains
- Fission
- Improve efficiency, segmentation
- Implantation Depth

Will explore:

- U+Th
- Diamond detectors
- Longer Term – Dubna SHE Factory ?

# Study of inputs for statistical model

S. M. Grimes

*Physics and Astronomy Department, Ohio University, Athens OH*

- Dominant reaction model for  $E/A \leq 10$  MeV relevant to astrophysical nuclear synthesis calculations
- Important to Energy production
- Useful in radioisotope production estimations for medical physics
- Level densities are a fundamental input in statistical model calculations
- Often based on neutron resonance counting
- Need spin cutoff parameter  $\sigma (= \langle J^2 \rangle^{1/2})$  to convert  $\frac{1}{2}+$  density to total
- Can also use evaporation spectra to deduce level density

## Models for spin cutoff parameter

1. Rigid body:  $\sigma^2 = 0.0145 * A^{5/3} * ((U - \delta)/a)^{1/2}$
2. Statistical mechanical :  $\sigma^2 = 6/\pi^2 ((U - \delta) * a)^{1/2} \langle m^2 \rangle$

a        is level density parameter

U        is excitation energy

$\langle m^2 \rangle$     is average z projection squared of orbits at Fermi-level

delta    is level density paring and shell shift

First form shows rise at closed shells. Second shows more structure with A and dip at closed shells

Most data points are from  $28 \leq A \leq 65$  and support tentatively statistical mechanical calculations. Need more data for  $A \geq 65$ .

Data for  $\sigma$  come from angular distribution measurements of compound reactions. If angular momentum brought and removed is substantial, at zero degree and at 180 degree, cross sections exceed 90 degree cross section.

Reactions with p,n as projectiles are nearly isotropic.

Alpha or  $^{12}\text{C}$  projectiles can give information about  $\sigma$ .

Evaporation spectra can give both sigma and level density information

Radioactive beams can produce compound systems farther from stability, but even  $^{12}\text{C}$  and  $^{24}\text{Mg}$  beams can reach nuclei 2-4 units from stability.

## Resources

- Beams of ions with  $E/A$  5-10 MeV both stable and radioactive
- Spectrometers for 1-25 MeV neutrons and protons and 4-34 MeV alphas.

# $\gamma$ - strength function in statistical nuclear physics

A. Voinov

*Physics and Astronomy Department, Ohio University, Athens OH*

Statistical model of nuclear reactions

Optical transmission coefficients

Level densities

Gamma strength functions

Most uncertain input parameters,  
leading to factor of 2 of uncertainty  
in reaction rate calculations.

Efforts should be directed to experimental study of  
nuclear structure in statistical regime where the nuclear behavior is  
determined by many individual levels

# $\gamma$ – strength function in continuum

$$f(E_\gamma) = \frac{\Gamma(E_\gamma)}{E_\gamma^3 D_i} \sim \frac{\sigma_{\text{abs}}(E_\gamma)}{E_\gamma}$$

Excitation energy

0

## Low-energy resonances in rare earth nuclei

A. Voinov et al. Phys.Rev. C 64, 044313(2001).

# Low-energy enhancement for Mo isotopes

M. Guttormsen et al,  
Physical Review C71, 044307(2005).

# Statements

- Origin of driving forces of electromagnetic transitions between complex excited states is still poorly studied .
- Work which has already done revealed new phenomena in the energy region below the particle separation threshold (resonances, low-energy enhancements).
- Experimental efforts are suggested to be directed to systematic study of average strength of  $\gamma$ -transitions from nuclear reactions with light and heavy ion beams
- The study of electromagnetic transitions in continuum for nuclei off of the stability line would be very important for future experiments with radioactive beams

# Resources

Low-energy beams (3-10 MeV/A) . High efficient charged particle spectrometers in combination with high efficient  $\gamma$ - detectors

- ANL, ATLAS, Gamma-sphere, Microball, GRETINA
- NSCL reaccelerated beams
- Texas Cyclotron, STARS Liberate spectrometer
- University low-energy accelerators
