The **Lorentz force equation** of a charged particle is given by (MKS Units):

$$\frac{d}{dt} \mathbf{p}_i(t) = q_i \left[ \mathbf{E}(\mathbf{x}_i, t) + \mathbf{v}_i(t) \times \mathbf{B}(\mathbf{x}_i, t) \right]$$

$m_i, \, q_i$ .... particle mass, charge  \hspace{2cm} i = \text{particle index}$

$x_i(t)$ .... particle coordinate \hspace{2cm} t = \text{time}$

$p_i(t) = m_i \gamma_i(t) v_i(t)$ .... particle momentum

$v_i(t) = \frac{d}{dt} x_i(t) = c \beta_i(t)$ .... particle velocity

$\gamma_i(t) = \frac{1}{\sqrt{1 - \beta_i^2(t)}}$ .... particle gamma factor

S1B: Applied Fields used to Focus, Bend, and Accelerate Beam

Transverse optics for focusing:

**Electric Quadrupole**

\[ \phi = -V_y \]

Electrodes Outside of Circle \( r = r_p \)
Electrodes: \( x^2 - y^2 = r_p^2 \)

**Magnetic Quadrupole**

\[ \phi = V_y \]

Conducting Beam Pipe: \( r = r_0 \)
Poles: \( xy = \pm \frac{r_0^2}{2} \)

**Solenoid**

Coil (Azimuthally Symmetric)

Dipole Bends:

**Electric** \( x \)-direction bend

\[ +V \]

\[ -V \]

\[ E^x \]

**Magnetic** \( x \)-direction bend

\[ B^x \]

Coils

Iron
Longitudinal Acceleration:

**RF Cavity**

Induction Cell

We will cover primarily transverse dynamics. Lectures by J.J. Barnard will cover acceleration and longitudinal physics:

- Acceleration influences transverse dynamics – not possible to fully decouple
S1C: Machine Lattice

Applied field structures are often arraigned in a regular (periodic) lattice for beam transport/acceleration:

- Sometimes functions like bending/focusing are combined into a single element

Example – Linear FODO lattice (symmetric quadrupole doublet)
Lattices for rings and some beam insertion/extraction sections also incorporate bends and more complicated periodic structures:

- Elements to insert beam into and out of ring further complicate lattice
- Acceleration cells also present (typically several RF cavities at one or more location)
S1D: Self fields

Self-fields are generated by the distribution of beam particles:
- Charges
- Currents

**Particle at Rest**
(pure electrostatic)

\[ \mathbf{B}^s = 0 \]

**Particle in Motion**

Obtain from Lorentz boost of rest-frame field:
see Jackson, *Classical Electrodynamics*

- Superimpose for all particles in the beam distribution
- Accelerating particles also radiate
  - We neglect electromagnetic radiation in this class
    (see: J.J. Barnard, *Intro Lectures*)
The electric ($\mathbf{E}^a$) and magnetic ($\mathbf{B}^a$) fields satisfy the Maxwell Equations. The linear structure of the Maxwell equations can be exploited to resolve the field into Applied and Self-Field components:

$$\mathbf{E} = \mathbf{E}^a + \mathbf{E}^s$$
$$\mathbf{B} = \mathbf{B}^a + \mathbf{B}^s$$

**Applied Fields** (often quasi-static $\frac{\partial}{\partial t} \approx 0$) $\mathbf{E}^a$, $\mathbf{B}^a$

Generated by elements in lattice

\[
\nabla \cdot \mathbf{E}^a = \frac{\rho^a}{\varepsilon_0} \\
\nabla \times \mathbf{B}^a = \mu_0 \mathbf{J}^a + \frac{1}{c^2} \frac{\partial}{\partial t} \mathbf{E}^a \\
\nabla \times \mathbf{E}^a = -\frac{\partial}{\partial t} \mathbf{B}^a \\
\n\nabla \cdot \mathbf{B}^a = 0
\]

$\rho^a = \text{applied charge density}$

$\mathbf{J}^a = \text{applied current density}$

$\frac{1}{\mu_0 \varepsilon_0} = c^2$

+ Boundary Conditions on $\mathbf{E}^a$ and $\mathbf{B}^a$

- Boundary conditions depend on the total fields $\mathbf{E}$, $\mathbf{B}$
  and if separated into Applied and Self-Field components, care can be required
- System often solved as static boundary value problem and source free in the vacuum transport region of the beam
\[ \nabla \equiv \hat{x} \frac{\partial}{\partial x} + \hat{y} \frac{\partial}{\partial y} + \hat{z} \frac{\partial}{\partial z} \]

- **Cartesian Representation**

\[ = \hat{r} \frac{\partial}{\partial r} + \hat{\theta} \frac{\partial}{\partial \theta} + \hat{z} \frac{\partial}{\partial z} \]

- **Cylindrical Representation**

\[ x = r \cos \theta \quad \hat{r} = \hat{x} \cos \theta + \hat{y} \sin \theta \]

\[ y = r \sin \theta \quad \hat{\theta} = -\hat{x} \sin \theta + \hat{y} \cos \theta \]

- **Abbreviated Representation**

\[ \frac{\partial}{\partial x} = \frac{\partial}{\partial x_\perp} + \hat{z} \frac{\partial}{\partial z} \]

- **Resolved Abbreviated Representation**

Resolved into Perpendicular (⊥) and Parallel (z) components

\[ x = \hat{x}x + \hat{y}y + \hat{z}z \]

\[ = x_\perp + \hat{z}z \]

\[ x_\perp \equiv \hat{x}x + \hat{y}y \]

In integrals, we denote:

\[ \int d^3 x \cdots = \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dy \int_{-\infty}^{\infty} dz \cdots = \int d^2 x_\perp \int_{-\infty}^{\infty} dz \cdots \]

\[ \int d^2 x_\perp \cdots = \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dy \cdots = \int_{0}^{\infty} dr \int_{-\pi}^{\pi} d\theta \cdots \]
**Self-Fields** *(dynamic, evolve with beam)*

Generated by particle of the beam rather than (applied) sources outside beam

\[
\nabla \cdot \mathbf{E}^s = \frac{\rho^s}{\varepsilon_0} \quad \nabla \times \mathbf{B}^s = \mu_0 \mathbf{J}^s + \frac{1}{c^2} \frac{\partial}{\partial t} \mathbf{E}^s \\
\n\nabla \times \mathbf{E}^s = -\frac{\partial}{\partial t} \mathbf{B}^s \quad \quad \nabla \cdot \mathbf{B}^s = 0
\]

\[\rho^s = \text{beam charge density} \]

\[= \sum_{i=1}^{N} q_i \delta[\mathbf{x} - \mathbf{x}_i(t)] \]

\[\mathbf{J}^s = \text{beam current density} \]

\[= \sum_{i=1}^{N} q_i \mathbf{v}_i(t) \delta[\mathbf{x} - \mathbf{x}_i(t)] \]

\[i = \text{particle index} \quad (N \text{ particles}) \]

\[q_i = \text{particle charge} \]

\[\mathbf{x}_i = \text{particle coordinate} \]

\[\mathbf{v}_i = \text{particle velocity} \]

\[\delta(\mathbf{x}) \equiv \delta(x) \delta(y) \delta(z) \]

\[\delta(x) \equiv \text{Dirac-delta function} \]

\[\sum_{i=1}^{N} \cdots = \text{sum over beam particles} \]

+ Boundary Conditions on $\mathbf{E}^s$ and $\mathbf{B}^s$

from material structures, radiation conditions, etc.
In accelerators, typically there is ideally a single species of particle:

\[ q_i \rightarrow q \]
\[ m_i \rightarrow m \]

Large Simplification!

Multi-species results in more complex collective effects

Motion of particles within axial slices of the “bunch” are highly directed:

\[ \beta_b(z)c \equiv \frac{1}{N'} \sum_{i=1}^{N'} \mathbf{v}_i \cdot \hat{z} \]

= Mean axial velocity of \( N' \) particles in beam slice

\[ \frac{d}{dt} \mathbf{x}_i(t) = \mathbf{v}_i(t) = \hat{z} \beta_b(z)c + \delta \mathbf{v}_i \]

\[ |\delta \mathbf{v}_i| \ll |\beta_b|c \quad \text{Paraxial Approximation} \]

There are typically many particles: (see S13, Vlasov Models for more details)

\[ \rho^s = \sum_{i=1}^{N} q_i \delta[\mathbf{x} - \mathbf{x}_i(t)] \]
\[ \mathbf{J}^s = \sum_{i=1}^{N} q_i \mathbf{v}_i(t) \delta[\mathbf{x} - \mathbf{x}_i(t)] \]

\[ \simeq \rho(\mathbf{x}, t) \quad \text{continuous charge-density} \]
\[ \simeq \beta_b c \rho(\mathbf{x}, t) \hat{z} \quad \text{continuous axial current-density} \]
The beam evolution is typically **sufficiently slow** (for heavy ions) where we can neglect radiation and approximate the self-field Maxwell Equations as:

See: J. J. Barnard, *Intro. Lectures: Electrostatic Approximation*

\[
\begin{align*}
E^s &= -\nabla \phi \\
B^s &= \nabla \times A \\
A &= \hat{z} \frac{\beta_b}{c} \phi \\
\nabla^2 \phi &= \frac{\partial}{\partial x} \cdot \frac{\partial}{\partial x} \phi = -\frac{\rho^s}{\epsilon_0} \\
\text{+ Boundary Conditions on } \phi
\end{align*}
\]

Vast Reduction of self-field model:
Approximation equiv to electrostatic interactions in frame moving with beam

But still complicated!

Resolve the **Lorentz force** acting on beam particles into **Applied** and **Self-Field** terms:

\[
F_i(x_i, t) = qE(x_i, t) + qv_i(t) \times B(x_i, t)
\]

**Applied:**

\[
F_i^a = qE_i^a + qv_i \times B_i^a
\]

**Self-Field:**

\[
F_i^s = qE_i^s + qv_i \times B_i^s
\]

**Applied:**

\[
F_i^a = F_i^a + F_i^s
\]

\[
E^a = E_i^a + E_i^s
\]

\[
B = B_i^a + B_i^s
\]

\[
E_i^a(x_i, t) \equiv E_i^a \text{ etc.}
\]
The self-field force can be simplified:

- See also: J.J. Barnard, Intro. Lectures

Plug in self-field forms:

\[ \mathbf{F}^s_i = q\mathbf{E}^s_i + q\mathbf{v}_i \times \mathbf{B}^s_i \]

\[ \simeq q \left[-\frac{\partial \phi}{\partial \mathbf{x}}\right]_i + (\beta_b c \hat{\mathbf{z}} + \delta \mathbf{v}_i) \times \left(\frac{\partial}{\partial \mathbf{x}} \times \hat{\mathbf{z}} \frac{\beta_b}{c} \phi\right)\bigg|_i \]

Neglect: Paraxial

\[ \ldots \bigg|_i \equiv \ldots \bigg|_{x=x_i} \]

Resolve into transverse (x and y) and longitudinal (z) components and simplify:

\[ \beta_b c \hat{\mathbf{z}} \times \left(\frac{\partial}{\partial \mathbf{x}} \times \hat{\mathbf{z}} \frac{\beta_b}{c} \phi\right)\bigg|_i = \beta_b^2 \hat{\mathbf{z}} \times \left(\frac{\partial}{\partial \mathbf{x}_\perp} \times \hat{\mathbf{z}} \phi\right)\bigg|_i \]

\[ = \beta_b^2 \hat{\mathbf{z}} \times \left(\frac{\partial \phi}{\partial y} \hat{\mathbf{x}} - \frac{\partial \phi}{\partial x} \hat{\mathbf{y}}\right)\bigg|_i \]

\[ = \beta_b^2 \left(\frac{\partial \phi}{\partial x} \hat{\mathbf{x}} + \frac{\partial \phi}{\partial y} \hat{\mathbf{y}}\right)\bigg|_i \]

\[ = \beta_b^2 \frac{\partial \phi}{\partial \mathbf{x}_\perp} \bigg|_i \]
also

\[- \frac{\partial \phi}{\partial \mathbf{x}} \bigg|_i = - \frac{\partial \phi}{\partial \mathbf{x}_\perp} \bigg|_i - \frac{\partial \phi}{\partial z} \bigg|_i \hat{z}\]

Together, these results give:

\[
\mathbf{F}^s_i = \begin{bmatrix} - \frac{q}{\gamma_b^2} \frac{\partial \phi}{\partial \mathbf{x}_\perp} \bigg|_i & - \hat{z}q \frac{\partial \phi}{\partial z} \bigg|_i \end{bmatrix}
\]

**Transverse** \hspace{2cm} **Longitudinal**

\[
\gamma_b \equiv \frac{1}{\sqrt{1 - \beta_b^2}} \hspace{4cm} \text{Axial relativistic gamma of beam}
\]

- Transverse and longitudinal forces have different axial gamma factors
- \(1/\gamma_b^2\) factor in transverse force shows the space-charge forces become weaker as axial beam kinetic energy increases
  - Most important in low energy (nonrelativistic) beam transport
  - Strong in/near injectors before much acceleration
/// Aside: Singular Self Fields

In *free space*, the beam potential generated from the singular charge density:

\[ \rho^s = \sum_{i=1}^{N} q_i \delta[x - x_i(t)] \]

is

\[ \phi(x) = \frac{q}{4\pi\varepsilon_0} \sum_{i=1}^{N} \frac{1}{|x - x_i|} \]

Thus, the force of a particle at \( x = x_i \) is:

\[ F_i = -q \frac{\partial \phi}{\partial x} \bigg|_i = \frac{q^2}{4\pi\varepsilon_0} \sum_{j=1}^{N} \frac{(x_i - x_j)}{|x_i - x_j|^{3/2}} \]

Which diverges due to the \( i = j \) term. This divergence is essentially “erased” when the continuous charge density is applied:

\[ \rho^s = \sum_{i=1}^{N} q_i \delta[x - x_i(t)] \rightarrow \rho(x, t) \]

\[ \text{Effectively removes effect of collisions} \]

See: J.J. Barnard, *Intro Lectures* for more details

- Find collisionless Vlasov model of evolution is often adequate
The particle equations of motion in $\mathbf{x}_i - \mathbf{v}_i$ phase-space variables become:

- Separate parts of $qE^a_i + qv_i \times B^a_i$ into transverse and longitudinal components.

**Transverse**

\[
\frac{d}{dt} \mathbf{x}_\perp = \mathbf{v}_\perp
\]

\[
\frac{d}{dt}(m\gamma_i \mathbf{v}_\perp) \approx qE^a_\perp + q\beta_b c \hat{\mathbf{z}} \times B^a_\perp + qB^a_{zi} \mathbf{v}_\perp \times \hat{\mathbf{z}} - q \left( \frac{1}{\gamma_b^2} \frac{\partial \phi}{\partial \mathbf{x}_\perp} \right)
\]

**Longitudinal**

\[
\frac{d}{dt} z_i = v_{zi}
\]

\[
\frac{d}{dt}(m\gamma_i v_{zi}) \approx qE^a_{zi} - q(v_{xi} B^a_{yi} - v_{yi} B^a_{xi}) - q \left( \frac{\partial \phi}{\partial z} \right)
\]

In the remainder of this (and most other) lectures, we analyze **Transverse Dynamics.** **Longitudinal Dynamics** will be covered in J.J. Barnard lectures.

- Except near injector, acceleration is typically slow
  - Fractional change in $\gamma_b, \beta_b$ small over characteristic transverse dynamical scales such as lattice period and betatron oscillation periods
- Regard $\gamma_b, \beta_b$ as specified functions given by the “acceleration schedule”
In transverse accelerator dynamics, it is convenient to employ the axial coordinate \( s \) of a particle in the accelerator as the independent variable:

- Need fields at lattice location of particle to integrate equations for particle trajectories

\[
\begin{align*}
    s & \equiv s_i + \int_{t_i}^{t} d\tilde{t} \ v_{zi}(\tilde{t}) \\
\end{align*}
\]

Transform:

\[
\begin{align*}
    t &= t_i \\
    s &= s_i \\
\end{align*}
\]

\[
\begin{align*}
    v_{zi} &= \frac{ds}{dt} \quad \Rightarrow \quad \frac{dx_i}{dt} &= \frac{ds}{ds} \frac{dx_i}{ds} = v_{zi} \frac{dx_i}{ds} = (\beta_b c + \delta v_{zi}) \frac{dx_i}{ds} \\
    \end{align*}
\]

Denote:

\[
\begin{align*}
    \dot{v}_{xi} &= \frac{dx_i}{dt} \approx \beta_b c x_i' \\
    \dot{v}_{yi} &= \frac{dy_i}{dt} \approx \beta_b c y_i' \\
\end{align*}
\]

Procedure becomes more complicated when bends present: see S1H
In the **paraxial approximation**, $x'$ and $y'$ can be interpreted as the (small magnitude) angles that the particles make with the longitudinal-axis:

$$x - \text{angle} = \frac{v_{xi}}{v_{zi}} \simeq \frac{v_{xi}}{\beta_b c} = x'_i$$

$$y - \text{angle} = \frac{v_{yi}}{v_{zi}} \simeq \frac{v_{yi}}{\beta_b c} = y'_i$$

The angles will be *small* in the paraxial approximation:

$$v_{xi}^2, \ v_{yi}^2 \ll \beta_b^2 c^2 \implies x'_i^2, \ y'_i^2 \ll 1$$

Since the spread of axial momentum/velocities is small in the paraxial approximation, a thin axial slice of the beam maps to a thin axial slice and $s$ can also be thought of as the axial coordinate of the slice in the accelerator lattice.

$$\beta_b \equiv \sum_{i=1}^{N'} \frac{v_{zi}}{c}$$

**slice**

$$s \simeq s_i + \int_{t_i}^{t} d\tilde{t} \ \beta_b(\tilde{t})$$
The coordinate $s$ can alternatively be interpreted as the axial coordinate of a reference (design) particle moving in the lattice.

- Design particle has no momentum spread.

It is often desirable to express the particle equations of motion in terms of $s$ rather than the time $t$.

- Makes it clear where you are in the lattice of the machine.
- Sometimes easier to use $t$ in codes when including many effects to high order.

\[
s \simeq s_i + \int_{t_i}^{t} d\tilde{t} \beta_b(\tilde{t})
\]
Transform transverse particle equations of motion to \( s \) rather than \( t \) derivatives

\[
\frac{d}{dt} \left( m\gamma_i \mathbf{v}_{\perp i} \right) \simeq q\mathbf{E}_{\perp i} + q\beta_b c \hat{\mathbf{z}} \times \mathbf{B}_{\perp i} + q\mathbf{B}_{zi}^{\perp} \mathbf{v}_{\perp i} \times \hat{\mathbf{z}} - q\gamma_2^{\perp} \frac{1}{\gamma_b} \frac{\partial \phi}{\partial \mathbf{x}_\perp} \bigg|_i
\]

Term 1

Term 2

Transform Terms 1 and 2 in the particle equation of motion:

Term 1: 
\[
\frac{d}{dt} \left( m\gamma_i \frac{d\mathbf{x}_{\perp i}}{dt} \right) = mv_{zi} \frac{d}{ds} \left( \gamma_i v_{zi} \frac{d}{ds} \mathbf{x}_{\perp i} \right)
\]

\[
= m\gamma_i \frac{v_{zi}^2}{ds^2} \frac{d^2}{ds^2} \mathbf{x}_{\perp i} + mv_{zi} \left( \frac{d}{ds} \mathbf{x}_{\perp i} \right) \frac{d}{ds} \left( \gamma_i v_{zi} \right)
\]

Approximate:

Term 1A:

\[
m\gamma_i v_{zi}^2 \frac{d^2}{ds^2} \mathbf{x}_{\perp i} \simeq m\gamma_b \beta_b^2 c^2 \frac{d^2}{ds^2} \mathbf{x}_{\perp i} = m\gamma_b \beta_b^2 c^2 \mathbf{x}''_{\perp i}
\]

Term 1B:

\[
mv_{zi} \left( \frac{d}{ds} \mathbf{x}_{\perp i} \right) \frac{d}{ds} \left( \gamma_i v_{zi} \right) \simeq m\beta_b c \left( \frac{d}{ds} \mathbf{x}_{\perp i} \right) \frac{d}{ds} \left( \gamma_b \beta_b c \right)
\]

\[
\simeq m\beta_b c^2 \left( \gamma_b \beta_b \right)' \mathbf{x}'_{\perp i}
\]
Using the approximations $1A$ and $1B$ gives for Term 1:

$$m \frac{d}{dt} \left( \gamma_i \frac{d\mathbf{x}_{\perp i}}{dt} \right) \simeq m \gamma_b \beta_b^2 c^2 \left[ \mathbf{x}_{\perp i}'' + \frac{(\gamma_b \beta_b)'}{\gamma_b \beta_b} \mathbf{x}_{\perp i}' \right]$$

Similarly we approximate in Term 2:

$$q B_{z_i}^a \mathbf{v}_{\perp i} \times \mathbf{\hat{z}} \simeq q B_{z_i}^a \beta_c \mathbf{x}_{\perp i}' \times \mathbf{\hat{z}}$$

Using the simplified expressions for Terms 1 and 2 obtain the reduced transverse equation of motion:

$$\mathbf{x}_{\perp i}'' + \frac{(\gamma_b \beta_b)'}{\gamma_b \beta_b} \mathbf{x}_{\perp i}' = \frac{q}{m \gamma_b \beta_b^2 c^2} \mathbf{E}_{\perp i}^a + \frac{q}{m \gamma_b \beta_b c} \mathbf{\hat{z}} \times \mathbf{B}_{\perp i}^a + \frac{q B_{z_i}^a}{m \gamma_b \beta_b c} \mathbf{x}_{\perp i}' \times \mathbf{\hat{z}} - \frac{q}{m \gamma_b^3 \beta_b^2 c^2} \frac{\partial \phi}{\partial \mathbf{x}_{\perp}} \bigg|_i$$

Will be analyzed extensively in lectures that follow in various limits to better understand solution properties.
S1F: Axial Particle Kinetic Energy

Relativistic particle kinetic energy is:

\[ \mathcal{E} = (\gamma - 1)mc^2 \]

\[ \gamma = \frac{1}{\sqrt{1 - \mathbf{v}^2/c^2}} \]

\[ \mathbf{v} = (\beta_b + \delta \beta_z) \hat{z} + \beta_\perp c \hat{x}_\perp \]

= Particle Velocity (3D)

For a directed paraxial beam with motion primarily along the machine axis the kinetic energy is essentially the axial kinetic energy \( \mathcal{E}_b \):

\[ \mathcal{E} = (\gamma_b - 1)mc^2 + \Theta \left( \frac{|\delta \beta_z|}{\beta_b}, \frac{\beta_\perp^2}{\beta_b^2} \right) \]

\[ \mathcal{E} \simeq \mathcal{E}_b \equiv (\gamma_b - 1)mc^2 \]

In nonrelativistic limit: \( \beta_b^2 \ll 1 \)

\[ \mathcal{E}_b \equiv (\gamma_b - 1)mc^2 = \frac{1}{2}m\beta_b^2 c^2 + \frac{3}{8}m\beta_b^4 c^2 + \cdots \]

\[ \simeq \frac{1}{2}m\beta_b^2 c^2 + \Theta(\beta_b^4) \]

Convenient units:

Electrons:

\[ m = m_e = 511 \frac{\text{keV}}{c^2} \]

Electrons rapidly relativistic due to relatively low mass
**Ions/Protons:**

\[ m = (\text{atomic mass}) \cdot m_u \quad m_u \equiv \text{Atomic Mass Unit} \]

\[ = 931.49 \ \text{MeV} \ \frac{c^2}{c^2} \]

**Note:**

\[ m_p = \text{Proton Mass} = 938.27 \ \text{MeV} \ \frac{c^2}{c^2} \quad m_p \simeq m_n \simeq 940 \ \text{MeV} \ \frac{c^2}{c^2} \]

\[ m_n = \text{Neutron Mass} = 939.57 \ \text{MeV} \ \frac{c^2}{c^2} \]

Approximate roughly for ions:

\[ m \simeq A m_u \quad A = \text{Mass Number} \quad (\text{Number of Nucleons}) \]

\[ m_p, m_n > m_u \quad \text{due to nuclear binding energy} \]

\[ \frac{\mathcal{E}_b/A}{m_u c^2} \simeq \gamma_b - 1 \quad \Longrightarrow \]

\[ \gamma_b = 1 + \frac{\mathcal{E}_b/A}{m_u c^2} \]

\[ \beta_b = \sqrt{1 - 1/\gamma_b^2} \]

**Energy/Nucleon** \( \mathcal{E}_b/A \) fixes \( \beta_b \) to set phase needs of RF cavities.

---

SM Lund, USPAS, 2015

Transverse Particle Dynamics 30
Contrast beam relativistic $\beta_b$ for electrons and protons/ions:

Electrons

Ions (and approx Protons)

Notes: 1) plots do not overlay, scale changed
2) Ion plot slightly off for protons since $m_u \neq m_p$

- Electrons become relativistic easier relative to protons/ions due to light mass
- Space-charge more important for ions than electrons (see Sec. S1D)
  - Low energy ions near injector expected to have strongest space-charge
S1G: Summary: Transverse Particle Equations of Motion

\[
\mathbf{x}''_\perp + \left(\frac{\gamma_b \beta_b}{\gamma_b \beta_b}\right)' \mathbf{x}'_\perp = \frac{q}{m \gamma_b \beta_b^2 c^2} \mathbf{E}^a + \frac{q}{m \gamma_b \beta_b c} \hat{\mathbf{z}} \times \mathbf{B}^a + \frac{q B^a_z}{m \gamma_b \beta_b c} \mathbf{x}'_\perp \times \hat{\mathbf{z}}
\]

\[
- \frac{q}{m \gamma_b^3 \beta_b^2 c^2} \frac{\partial}{\partial \mathbf{x}_\perp} \phi
\]

\[
\mathbf{E}^a = \text{Applied Electric Field} \quad \mathbf{B}^a = \text{Applied Magnetic Field} \quad I \equiv \frac{d}{ds} \quad \gamma_b \equiv \frac{1}{\sqrt{1 - \beta_b^2}}
\]

\[
\nabla^2 \phi = \frac{\partial}{\partial \mathbf{x}} \cdot \frac{\partial}{\partial \mathbf{x}} \phi = -\frac{\rho}{\epsilon_0}
\]

+ Boundary Conditions on \( \phi \)

Drop particle \( i \) subscripts (in most cases) henceforth to simplify notation
Neglects axial energy spread, bending, and electromagnetic radiation \( \gamma \)–factors different in applied and self-field terms:

\[
In-q \frac{m \gamma_b^3 \beta_b^2 c^2}{\epsilon_0} \frac{\partial}{\partial \mathbf{x}} \phi, \text{ contributions to } \gamma_b^3:
\]

\[
\gamma_b \implies \text{Kinematics}
\]

\[
\gamma_b^2 \implies \text{Self-Magnetic Field Corrections (leading order)}
\]
Much of transverse accelerator physics centers on understanding the evolution of beam particles in 4-dimensional $x$-$x'$ and $y$-$y'$ phase space. Typically, restricted 2-dimensional phase-space projections in $x$-$x'$ and/or $y$-$y'$ are analyzed to simplify interpretations:

When forces are linear, particles tend to move on ellipses of constant area. - Ellipse may elongate/shrink and rotate as beam evolves in lattice.

Nonlinear force components distort orbits and cause undesirable effects. - Growth in effective phase-space area reduces focusability.
The “effective” phase-space volume of a distribution of beam particles is of fundamental interest.

We will find in statistical beam descriptions that:

- **Larger/Smaller** beam phase-space areas (Larger/Smaller emittances) ↔ **Harder/Easier** to focus beam on **small** final spots

Effective area measure in $x$-$x'$ phase-space is the $x$-emittance:

Statistical ”Area” $\sim \pi \varepsilon_x$

$$\varepsilon_x = 4[\langle x^2 \rangle_{\perp} \langle x'^2 \rangle_{\perp} - \langle xx' \rangle_{\perp}^2]^{1/2}$$
Much of advanced accelerator physics centers on preserving beam quality by understanding and controlling emittance growth due to nonlinear forces arising from both space-charge and the applied focusing. In the remainder of the next few lectures we will review the physics of a single particles moving in linear applied fields with emphasis on transverse effects. Later, we will generalize concepts to include forces from space-charge in this formulation and nonlinear effects from both applied and self-fields.
S1I: Bent Coordinate System and Particle Equations of Motion with Dipole Bends and Axial Momentum Spread

The previous equations of motion can be applied to dipole bends provided the \( x, y, z \) coordinate system is fixed. It can prove more convenient to employ coordinates that follow the beam in a bend.

- Orthogonal system employed called Frenet-Serret coordinates

\[ \Theta = \text{Bend Angle} \]
\[ R = \text{Bend Radius} \]
\[ s = \text{Reference Trajectory Coordinate} \]
In this perspective, dipoles are adjusted given the design momentum of the reference particle to bend the orbit through a radius \( R \).

- Bends usually only in one plane (say \( x \))
  - Implemented by a dipole applied field: \( E_x^a \) or \( B_y^a \)
- Easy to apply material analogously for \( y \)-plane bends, if necessary

Denote:

\[
p_0 = m\gamma_b\beta_b c = \text{design momentum}
\]

Then a magnetic \( x \)-bend through a radius \( R \) is specified by:

\[
\mathbf{B}^a = B_y^a \hat{y} = \text{const in bend}
\]

\[
\frac{1}{R} = \frac{qB_y^a}{p_0}
\]

The particle rigidity is defined as ( \([B\rho]\) read as one symbol called “B-Rho”):

\[
[B\rho] \equiv \frac{p_0}{q} = \frac{m\gamma_b\beta_b c}{q}
\]

is often applied to express the bend result as:

\[
\frac{1}{R} = \frac{B_y^a}{[B\rho]}
\]

Analogous formula for Electric Bend will be derived in problem set.
Comments on bends:

- $R$ can be positive or negative depending on sign of $B_y^a/[B \rho]$
- For straight sections, $R \rightarrow \infty$ (or equivalently, $B_y^a = 0$)
- Lattices often made from discrete element dipoles and straight sections with separated function optics
  - Bends can provide “edge focusing”
  - Sometimes elements for bending/focusing are combined
- For a ring, dipoles strengths are tuned with particle rigidity/momentum so the reference orbit makes a closed path lap through the circular machine
  - Dipoles adjusted as particles gain energy to maintain closed path
  - In a Synchrotron dipoles and focusing elements are adjusted together to maintain focusing and bending properties as the particles gain energy. This is the origin of the name “Synchrotron.”
- Total bending strength of a ring in Tesla-meters limits the ultimately achievable particle energy/momentum in the ring
For a magnetic field over a path length $S$, the beam will be bent through an angle:

$$\Theta = \frac{S}{R} = \frac{SB_y^a}{[B \rho]}$$

To make a ring, the bends must deflect the beam through a total angle of $2\pi$:

- Neglect any energy gain changing the rigidity over one lap

\[
2\pi = \sum_{i, \text{Dipoles}} \Theta_i = \sum_i \frac{S_i}{R_i} = \sum_i \frac{S_i B_y^{a,i}}{[B \rho]}
\]

For a symmetric ring, $N$ dipoles are all the same, giving for the bend field:

- Typically choose parameters for dipole field as high as technology allows for a compact ring

\[
B_y^a = 2\pi \frac{[B \rho]}{NS}
\]

For a symmetric ring of total circumference $C$ with straight sections of length $L$ between the bends:

- Features of straight sections typically dictated by needs of focusing, acceleration, and dispersion control

\[
C = NS + NL
\]
Example: Typical separated function lattice in a Synchrotron
Focus Elements in Red
Bending Elements in Green

Ring Lattice: 12 Periods
(SIS-18, GSI)
18 Tesla-Meter

Lattice Period Sector

One Lattice Period (separated function)

Triplet Quadrupoles Bending Dipoles
For “off-momentum” errors:

\[
p_s = p_0 + \delta p
\]

\[
p_0 = m\gamma_v/\beta_v c = \text{design momentum}
\]

\[
\delta p = \text{off- momentum}
\]

This will modify the particle equations of motion, particularly in cases where there are bends since particles with different momenta will be bent at different radii.

Not usual to have acceleration in bends.
- Dipole bends and quadrupole focusing are sometimes combined.

Common notation:

\[
\delta \equiv \frac{\delta p}{p_0} = \text{Fractional Momentum Error}
\]
Derivatives in accelerator Frenet-Serret Coordinates

Summarize results only needed to transform the Maxwell equations, write field derivatives, etc.

- Reference: Chao and Tigner, *Handbook of Accelerator Physics and Engineering*

\[ \Psi(x, y, s) = \text{Scalar} \]

\[ \mathbf{V}(x, y, s) = V_x(x, y, s)\hat{x} + V_y(x, y, s)\hat{y} + V_s(x, y, s)\hat{s} = \text{Vector} \]

**Vector Dot and Cross-Products:** \((\mathbf{V}_1, \mathbf{V}_2 \text{ Two Vectors})\)

\[ \mathbf{V}_1 \cdot \mathbf{V}_2 = V_{1x}V_{2x} + V_{1y}V_{2y} + V_{1s}V_{2s} \]

\[ \mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \hat{x} & \hat{y} & \hat{s} \\ V_{1x} & V_{1y} & V_{1s} \\ V_{2x} & V_{2y} & V_{2s} \end{vmatrix} \]

\[ = (V_{1x}V_{2s} - V_{1s}V_{2x})\hat{x} + (V_{1s}V_{2x} - V_{1x}V_{2s})\hat{y} + (V_{1x}V_{2y} - V_{1y}V_{2x})\hat{s} \]

**Elements:**

\[ d^2x_\perp = dxdy \]

\[ d^3x_\perp = \left(1 + \frac{x}{R}\right)dxdyds \]

\[ d\ell = \hat{x}dx + \hat{y}dy + \hat{s}\left(1 + \frac{x}{R}\right)ds \]
Gradient:
\[ \nabla \Psi = \hat{x} \frac{\partial \Psi}{\partial x} + \hat{y} \frac{\partial \Psi}{\partial y} + \hat{s} \frac{1}{1 + x/R} \frac{\partial \Psi}{\partial s} \]

Divergence:
\[ \nabla \cdot \mathbf{V} = \frac{1}{1 + x/R} \frac{\partial}{\partial x} [(1 + x/R)V_x] + \frac{\partial V_y}{\partial y} + \frac{1}{1 + x/R} \frac{\partial V_s}{\partial s} \]

Curl:
\[ \nabla \times \mathbf{V} = \hat{x} \left( \frac{\partial V_s}{\partial y} - \frac{1}{1 + x/R} \frac{\partial V_y}{\partial s} \right) + \hat{y} \frac{1}{1 + x/R} \left( \frac{\partial V_x}{\partial s} - \frac{\partial}{\partial x} [(1 + x/R)V_s] \right) \]
\[ + \hat{s} (1 + x/R) \left( \frac{\partial V_y}{\partial x} - \frac{\partial V_x}{\partial y} \right) \]

Laplacian:
\[ \nabla^2 \Psi = \frac{1}{1 + x/R} \frac{\partial}{\partial x} \left[ (1 + \frac{x}{R}) \frac{\partial \Psi}{\partial x} \right] + \frac{\partial^2 \Psi}{\partial y^2} + \frac{1}{1 + x/R} \frac{\partial}{\partial s} \left[ \frac{1}{1 + x/R} \frac{\partial \Psi}{\partial s} \right] \]
Transverse particle equations of motion including bends and “off-momentum” effects

- See texts such as Edwards and Syphers for guidance on derivation steps
- Full derivation is beyond needs/scope of this class

\[
\begin{align*}
x'' + \frac{(\gamma_b \beta_b)'}{(\gamma_b \beta_b)} x' + \left[ \frac{1}{R^2(s)} \frac{1 - \delta}{1 + \delta} \right] x &= \frac{\delta}{1 + \delta} \frac{1}{R(s)} + \frac{q}{m \gamma_b \beta_b^2 c^2} \frac{E_x^a}{(1 + \delta)^2} \\
- \frac{q}{m \gamma_b \beta_b c} \frac{B_y^a}{1 + \delta} + \frac{q}{m \gamma_b \beta_b c} \frac{B_s^a}{1 + \delta} y' &= \frac{q}{m \gamma_b \beta_b^2 c^2} \frac{E_y^a}{(1 + \delta)^2} + \frac{q}{m \gamma_b \beta_b c} \frac{B_x^a}{1 + \delta} \\
y'' + \frac{(\gamma_b \beta_b)'}{(\gamma_b \beta_b)} y' &= \frac{q}{m \gamma_b \beta_b^2 c^2} \frac{E_y^a}{(1 + \delta)^2} + \frac{q}{m \gamma_b \beta_b c} \frac{B_x^a}{1 + \delta} \\
- \frac{q}{m \gamma_b \beta_b c} \frac{B_s^a}{1 + \delta} x' &= \frac{q}{m \gamma_b \beta_b^2 c^2} \frac{1}{1 + \delta} \frac{\partial \phi}{\partial y}
\end{align*}
\]

\[
p_0 = m \gamma_b \beta_b c = \text{Design Momentum}
\]

\[
\delta \equiv \frac{\delta p}{p_0} = \text{Fractional Momentum Error}
\]

Comments:

- Design bends only in \(x\) and \(B_y^a, \ E_x^a\) contain no dipole terms (design orbit)
  - Dipole components set via the design bend radius \(R(s)\)
- Equations contain only low-order terms in momentum spread \(\delta\)
Comments continued:

- Equations are often applied linearized in $\delta$
- Achromatic focusing lattices are often designed using equations with momentum spread to obtain focal points independent of $\delta$ to some order $x$ and $y$ equations differ significantly due to bends modifying the $x$-equation when $R(s)$ is finite
- It will be shown in the problems that for electric bends:
  \[
  \frac{1}{R(s)} = \frac{E^a_x(s)}{\beta_b c [B \rho]}
  \]
- Applied fields for focusing: $E^a_x, B^a_y, B^a_s$
  - must be expressed in the bent $x,y,s$ system of the reference orbit
  - Includes error fields in dipoles
- Self fields may also need to be solved taking into account bend terms
  - Often can be neglected in Poisson's Equation
  \[
  \left\{ \frac{1}{1 + x/R} \frac{\partial}{\partial x} \left[ \left( 1 + \frac{x}{R} \right) \frac{\partial}{\partial x} \right] + \frac{\partial^2}{\partial y^2} + \frac{1}{1 + x/R} \frac{\partial}{\partial s} \left[ \frac{1}{1 + x/R} \frac{\partial}{\partial s} \right] \right\} \phi = -\frac{\rho}{\varepsilon_0}
  \]
  if $R \to \infty$
  reduces to familiar:
  \[
  \left\{ \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial s^2} \right\} \phi = -\frac{\rho}{\varepsilon_0}
  \]
Appendix A: Gamma and Beta Factor Conversions

It is frequently the case that functions of the relativistic gamma and beta factors are converted to superficially different appearing forms when analyzing transverse particle dynamics in order to more cleanly express results. Here we summarize useful formulas in that come up when comparing various forms of equations. Derivatives are taken wrt the axial coordinate \( s \) but also apply wrt time \( t \).

Results summarized here can be immediately applied in the paraxial approximation by taking:

\[
\nu = |\mathbf{v}| \simeq v_b = \beta_b c \quad \implies \quad \beta \simeq \beta_b
\]

\[
\gamma \simeq \gamma_b
\]

Assume that the beam is forward going with \( \beta \geq 0 \):

\[
\gamma \equiv \frac{1}{\sqrt{1 - \beta^2}}
\]

\[
\gamma^2 = \frac{1}{1 - \beta^2}
\]

\[
\beta = \frac{1}{\gamma} \sqrt{\gamma^2 - 1}
\]

\[
\beta^2 = 1 - 1 / \gamma^2
\]

A commonly occurring acceleration factor can be expressed in several ways:

- Depending on choice used, equations can look quite different!

\[
\frac{(\gamma \beta)'}{(\gamma \beta)} = \frac{\gamma'}{\gamma} + \frac{\beta'}{\beta} = \frac{\gamma'}{\gamma \beta^2}
\]
Axial derivative factors can be converted using:

\[ \gamma' = \frac{\beta \beta'}{(1 - \beta^2)^{3/2}} \quad \beta' = \frac{\gamma'}{\gamma^2 \sqrt{\gamma^2 - 1}} \]

Energy factors:

\[ \mathcal{E}_{\text{tot}} = \gamma mc^2 = \mathcal{E} + mc^2 \]

\[ \gamma \beta = \sqrt{\left( \frac{\mathcal{E}}{mc^2} \right)^2 + 2 \left( \frac{\mathcal{E}}{mc^2} \right)} \]

Rigidity:

\[ [B \rho] = \frac{p}{q} = \frac{\gamma mv}{q} = \frac{mc}{q} \gamma \beta = \frac{mc}{q} \sqrt{\left( \frac{\mathcal{E}}{mc^2} \right)^2 + 2 \left( \frac{\mathcal{E}}{mc^2} \right)} \]
